

Concept Designs

1) Steel wool on wedge

+ Acts as a rust deterrent (Rusts quick but protects the metal parts)

+ If placed properly could get the opposing wedge stuck in one way or another

+ Can cause slight rounding of opponents wedge (constant scraping of opponents wedge)

* ~~Loose filaments can lead to~~

- If the steel wool gets swept off we would get disqualified as they would scatter across the field

2) See-Through (Transparent Roofing)

+ Using acrylic as a sort of roof component, bonus points for design and looks good for presentation

- Mechanism needed for hatching roof on chassis.

3) Wheel Protection

Cap like structure

- + Additional Protection for the wheels
- Could take more filament + lead to complications with the wheel placement.

4) Side flaps

S.V

F.V

when opened

- + Prevent flanking from opponent
- + Act as a deterrent for full blown ramming from the sides as they provide first line of defense
- Takes an extra pin
- Durability concerns of the flap.

4) Diamond design

- + Use of ~~multi~~ omnidirectional wheels and diamond chassis design leads to a highly mobile defensive design.
- + High spinning chassis can provide sufficient pushing force
- Unconventional design, ~~is~~ not very aggressive support.

5) Hidden wheels

B.V

- + Makes sure wheels are not exposed and chassis redesign can lead to little to no weaknesses
- Less overall space will be available in the chassis inside for components.

6) Detachable wedge (By screw)

- + \$: Gives us chance to change wedge in case of physical defect / dent.
- Screw type placement might take time to replace.
